$T$, a base $B$ and its base states, voters sorted (voter lex-ordering)
Is Aut($T$) non-trivial?
no
Search every base state
yes
Anchoring: one representative per orbit of ordered pairs (orbit anchoring) or of vertices (vertex anchoring), whichever has fewer orbits
Are all the representatives in $B$?
no
Enforce anchoring during the search only (not available to SAT cubes)
yes
Discard the base states in which no voter is anchored
Does a subgroup $H$ of Aut($T$) map some $C \subseteq B$ onto itself?
no
yes
Keep the base states whose restriction to $C$ is the chosen base state of its $H$-orbit (base-stabilizer quotient)
Does $H$ fix every representative?
no
Use whichever of anchoring and quotient leaves fewer base states
yes
Use both (quotient, part (b) or (c))
Search the remaining base states, in parallel
